FORAGE SUITABILITY GROUP Overflow

FSG No.: G102AY500SD

Major Land Resource Area: 102A - Rolling Till Prairie

Physiographic Features

The soils in this group are generally found in nearly level to gently sloping positions on stream terraces, fan remnants, and flood plains, and in swales and drainage ways on uplands. They receive beneficial additional moisture as run-on from up slope, or from flooding.

	<u>Minimum</u>	<u>Maximum</u>
Elevation (feet):	980	1970
Slope (percent):	0	3
Flooding:		
Frequency:	None	Frequent
Duration:	None	Brief
Ponding:		
Depth (inches):		
Frequency:	None	None
Duration:	None	None
Runoff Class:	Negligible	Medium

Climatic Features

This group occurs in a mid-continental climate characterized by wide seasonal temperature and precipitation fluctuations and extremes.

Annual precipitation varies widely from year to year in MLRA 102A. Average annual precipitation for all climate stations listed below is about 23 inches. About 75 percent of that occurs during the months of April through September. On average, there are about 31 days with greater than .1 inches of precipitation during the same timeframe. Precipitation is less than needed for optimum forage production and is the single largest factor limiting production from this group on non-irrigated lands.

Average annual snowfall ranges from 36 inches at Britton to 48 inches at Tracy. Snow cover at depths greater than 1 inch range from 56 days at Milbank to 105 days at Morris.

Average July temperatures are about 72°F and average January temperatures are about 11°F. Recorded temperature extremes in the MLRA during the years 1961 to 1990 are a low of -40 at Brookings and a high of 108 recorded at both Britton and Milbank. The MLRA lies in USDA Plant Hardiness Zones 4a and 4b.

Average annual wind speeds range from about 8 mph in the eastern part of the MLRA to about 11 mph in the west. The highest wind speeds occur during March through May. It is cloudy about 154 days a year in the west and 166 days in the east. Average morning relative humidity in June is about 86 percent and average afternoon humidity is 59 percent.

The climate data listed in the tables below represent high and low ranges and averages for the climate stations and dates listed. For additional climate data, access the National Water and Climate Center at http://www.wcc.nrcs.usda.gov.

Soil Interpretations

This group consists of very deep, mostly moderately well drained, moderately fine to medium textured soils formed from glacial till or alluvial deposits. Available water capacity is high. Many of these soils have a seasonal watertable within three feet of the surface which benefits deep rooted plants.

Drainage Class:	Moderately well drained	To	Well drained

G - Good adaptation for forage production on this group of soils in this MLRA

Production Estimates

Production estimates listed here should only be used for making general management recommendations. Onsite production information should always be used for making detailed planning and management recommendations.

The high forage production estimates listed below are based on dense, vigorous stands of climatically adapted, superior performing cultivars. They are properly fertilized for high yields, and pest infestations are kept below economic thresholds. Mechanical harvests are managed to maintain stand life by cutting at appropriate stages of maturity and harvest intervals. If grazed, optimum beginning and ending grazing heights are adhered to. Adequate time is allowed for plant recovery before entering winter dormancy under both uses.

F - Fair adaptation but will not produce at its highest potential

NS - Species is not adapted to the site and should not be planted

Pastureland and Hayland Interpretations

The production estimates listed below represent total annual above ground plant production on an air-dry-matter basis. Estimates of hay and grazing yields can be calculated from these numbers by multiplying them by a harvest efficiency. A 70 percent harvest efficiency is commonly used when converting to hay yields. Pasture harvest efficiency is highly dependent on the grazing management system applied, ranging from 25 to 50 percent.

	Drylan	d	Irrigated		
Forage Crop	Management	Intensity	Management	Intensity	
	<u>High</u>	Low	<u>High</u>	Low	
	(lbs/ac)	(lbs/ac)	(lbs/ac)	(lbs/ac)	
Alfalfa	12600	5400			
Alfalfa/Intermediate wheatgrass	12000	4900	17100	10300	
Alfalfa/Orchardgrass	12000	4900	17100	10300	
Alfalfa/Smooth bromegrass	12000	4900	17100	10300	
Big bluestem	9400	4900			
Intermediate wheatgrass	8000	4000	14300	8600	
Orchardgrass	8000	4000	14300	8600	
Smooth bromegrass	8000	4000	14300	8600	
Switchgrass	9400	4900			

Forage Growth Curves

Growth curves estimate the seasonal distribution of growth of the various forage crops. They indicate when the forages may be available for grazing or mechanical harvest.

Soil Limitations

These soils have few limitations to the production of climatically adapted forage crops. Production potential is high. Flooding is a potential hazard to some of these soils. Also, all of these soils receive additional moisture, so the potential exists for soil compaction from grazing or operating machinery on them when wet.

Management Interpretations

Soils in this group that are subject to flooding can have forage production adversely impacted if it occurs during the spring or growing season. Flooding duration, or the time period plants are under water, is more important than flooding frequency for the survival of forage crops. If these soils do flood it is generally for only a brief time. Exclude livestock and machinery during extended periods of soil wetness to reduce soil compaction. When establishing new stands or renovating stands select highly productive species and varieties that can make best use of the additional soil moisture this group receives.
